My study investigates the history of the landscapes of the Körös region in Békés County. This region is located along the river Körös, which is a tributary of the Tisza River. The Körös has played a significant role during the prehistoric and early medieval periods. The Tisza River's importance has diminished over time, while the Körös has continued to be a vital resource for the local population. The study aims to explore the changes that have occurred in the landscape and the economy of the region due to the regulation of the river.

In the 19th century, the Körös was dammed and its course was modified for agricultural purposes. This has resulted in the formation of artificial lakes and changes in the local environment. The study also examines the impact of these changes on the economy of the region, particularly in relation to farming and fishing.

The archaeological research conducted in the region has revealed evidence of human settlement and activity over a long period of time. The study uses aerial images and maps to track changes over the past century, providing insights into the evolution of the landscape and the economy of the region.
